## Definition of typical, minimum and maximum values

Minimum and maximum values for specified limiting and safety conditions have to be understood as such as well as values shown in "typical" graphs.

On the other hand, measured values are part of a statistical distribution that can be specified by an interval with upper and lower limits and a probability for measured values to lie within this interval.

Unless otherwise stated (e.g. "100 % tested"), the LEM definition for such intervals designated with "min" and "max" is that the probability for values of samples to lie in this interval is 99.73 %.

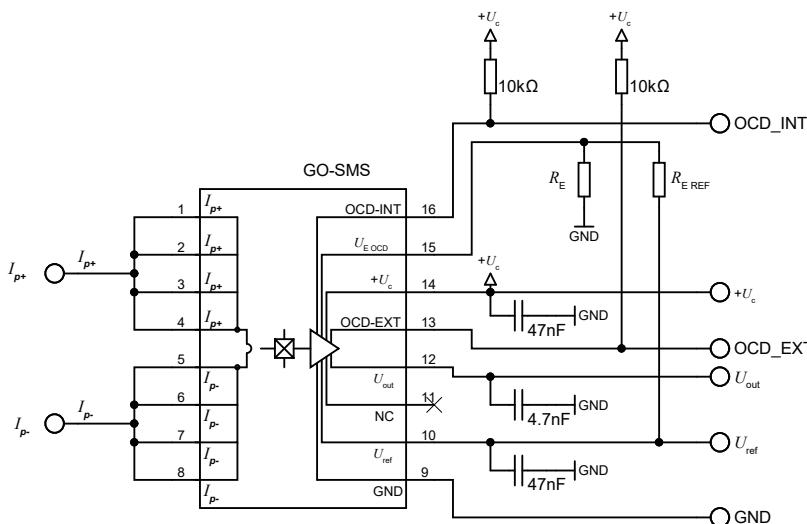

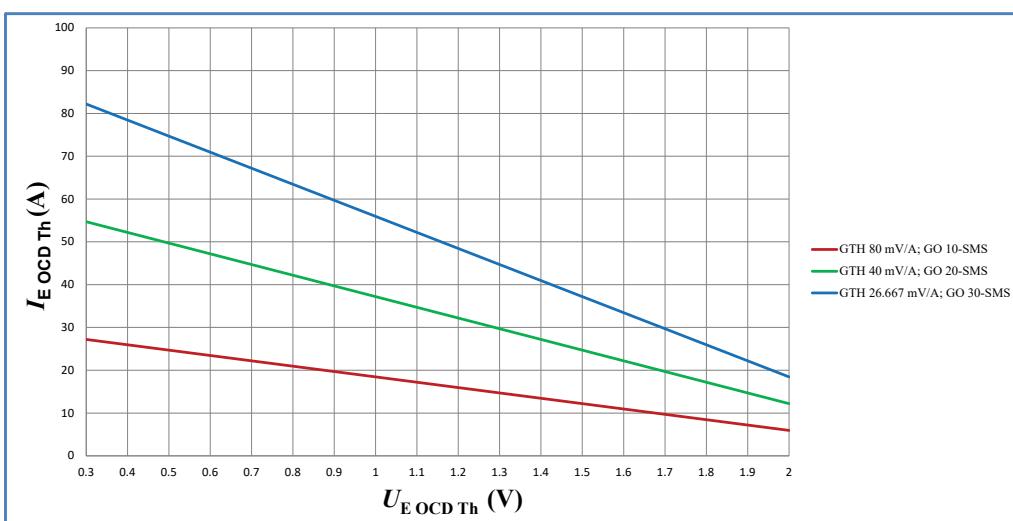

For a normal (Gaussian) distribution, this corresponds to an interval between -3 sigma and +3 sigma. If "typical" values are not obviously mean or average values, those values are defined to delimit intervals with a probability of 68.27 %, corresponding to an interval between -sigma and +sigma for a normal distribution.

Typical, maximal and minimal values are determined during the initial characterization of the product.

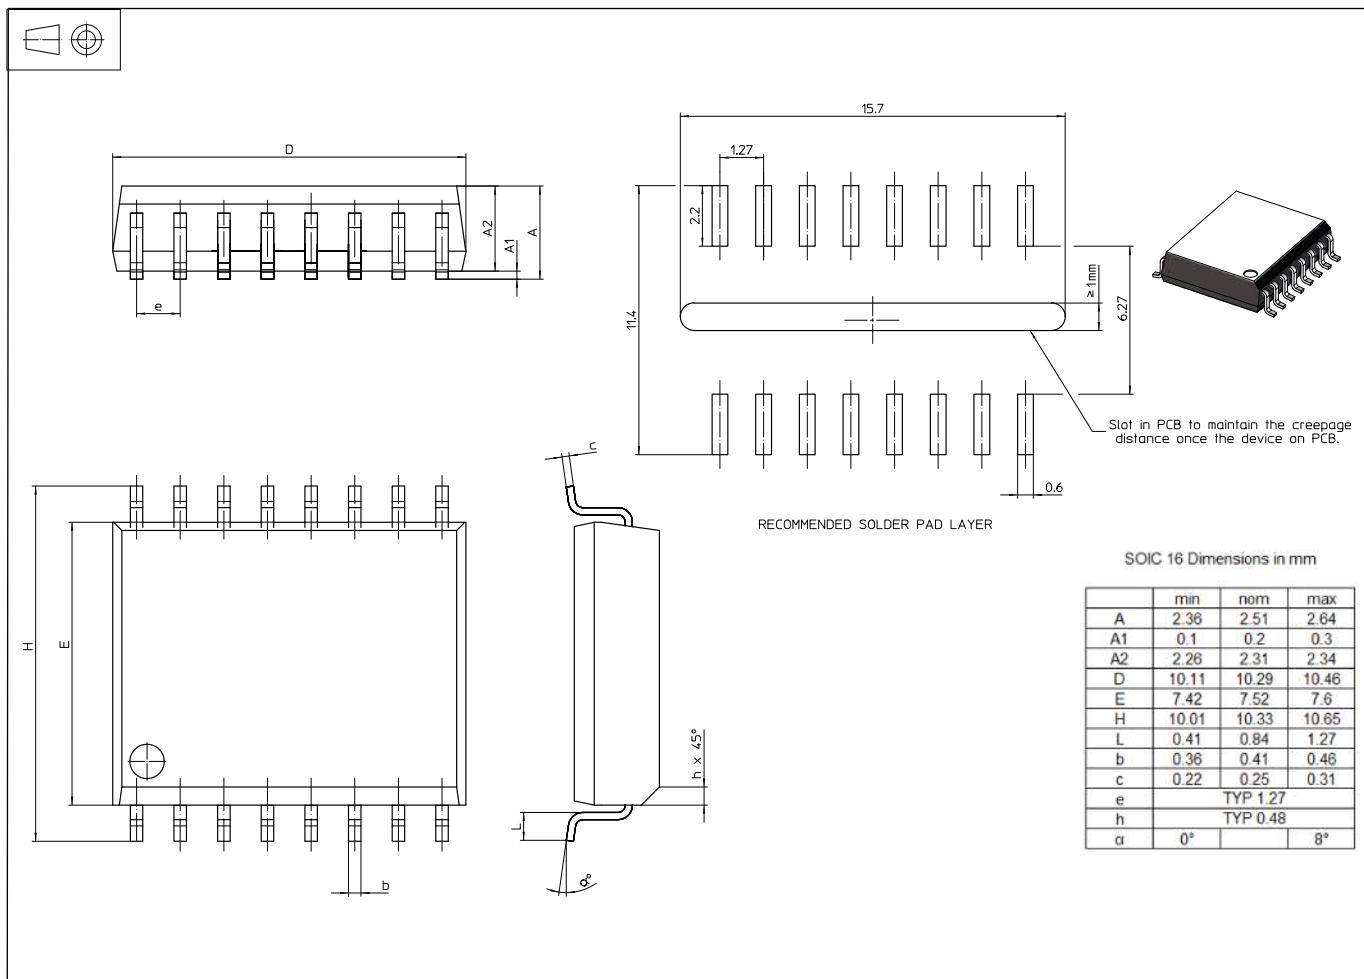

## External overcurrent detection

Parameter	Symbol	Unit	Specification			Conditions
			Min	Typical	Max	
External OCD voltage	$U_{\text{E OCD}}$	V	0.3		2	
External OCD output on resistance to ground	$R_{\text{on E OCD}}$	$\Omega$	35	200	300	2.5 on pin
External OCD delay time	$t_{\text{D E OCD}}$	$\mu\text{s}$		10		To be added to the sensor delay time
External OCD output hold time	$t_{\text{hold E OCD}}$	$\mu\text{s}$		10		
External OCD threshold error	$\varepsilon_{\text{E OCD Th}}$	%		$\pm 5$		Switch point error between $U_{\text{out}}$ and $U_{\text{E OCD}}$

External OCD detection threshold  $I_{\text{E OCD Th}}$ :

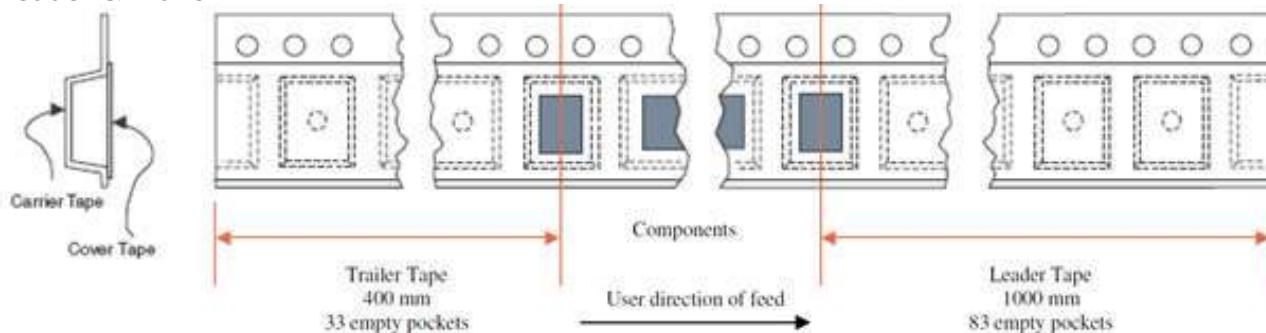

$$I_{\text{E OCD Th}} = \frac{(U_{\text{ref}} - U_{\text{E OCD}})}{S_N} \times 1000 \quad U_{\text{E OCD Th}} = \frac{R_E}{R_E + R_{\text{ref}}} \times U_{\text{ref}}$$
